Feature Extraction.

Feature extraction is a fundamental step in any object recognition algorithm. It refers to the process of extracting useful information referred to as features from an input image. The extracted features must be representative in nature, carrying important and unique attributes of the image.

Feature extraction refers to the process of transforming raw data into numerical features that can be processed while preserving the information in the original data set. It yields better results than applying machine learning directly to the raw data. Feature extraction can be accomplished manually or automatically:

The datasets_feature function can be run on multiple machines in parallel to speed up feature extraction. This function handles the complete pipeline of building a dictionary (for bag-of-words features), coding features to the dictionary, and pooling them together in a spatial pyramid.

Matlab Code

[features,validPoints] = extractFeatures(I,point s) returns extracted feature vectors, also known as descriptors, and their corresponding locations, from a binary or intensity image. The function derives the descriptors from pixels surrounding an interest point. The pixels represent and match features specified by a single-point location.
